## POLISH MICROBIOLOGISTS CLAIM PROGRESS

Polish bacteriologists are becoming more and more proficient in conquering disease-carrying bacteria and its carriers. The well-known microbiologist, Dr Parnas, professor of the Department of Microbiology at UMCS (Maria Curie-Sklodowska University), made the following statement:

From the moment that our laboratories were built in 1944, we have been working on the most efficient methods of combating contagious diseases. We were the first to announce results on the use of streptomycin in treating glanders (nosacizna). As a result of this research, glanders, transmitted to man by animals, is now completely curable. Whereas we work to overcome glanders, the American pseudoscientists threaten to spread this horrible disease among people.

We are conducting continuous research in our laboratories for an efficient method to combat brucellosis (brucelloza). We have made considerably progress in detecting the virus of this disease and in controlling it by using modernized and standardized methods. We have developed a preparation called "Brucellinie - F5" for better diagnosis and treatment of this disease, particularly in humans. Meanwhile, the so-called scientists of the declining capitalist world have added brucellosis to their arsenal of genocidal bacteriological weapons.

By tedious research we have been looking for the virus which could be used against such pests and carriers of diseases as bedbugs, flies, and cockroaches. We have declared bacteriological varfare against pests. Today, we hear that the warmongers are studying insects not for utilitarian but for genocidal purposes, to spread epidemics not among pests but among children, women, and the aged.

Working for humanity we have been conducting research on infections of young animals. This research has permitted us to organize a fight against diseases at the state farms and producers' cooperatives.

RESTRICTED

The turning point in our research was brought about by the contribution of Soviet scientists, who pursue science for the single purpose of subordinating the microbes to the will of man and for the good of man.

Microbiology is developing along entirely different lines in the USA. There man, if one can apply this term to war criminals armed with the most modern bacteriological techniques, alters the nature of microbes by multiplying their virulence, spread, and contagious properties, to bring about destruction of man.
